Using cURL to retrieve the output of a file only takes a few more characters. Saving a file with a remote file name can save the output to a local file in the current working directory. Using the output redirection operator in Linux, you can use the output append operator to write the output into a specific file. If the target server responded with the HTTP redirection code (3xx) for the requested file, the local file you downloaded would be empty. If you want to download multiple files with a single command, you have to add the sizeof-r to the cURL.Husband / Father / Software EngineerIf you have ever used cURL to retrieve the output of a file, believe me, saving that output to a file only takes a few more characters.Example #1: Saving a file with the remote file nameYou can use the -O or --remote-name option to save the output to a local file in the current working directory using the remote file name.\$ curl -O this example, the ./README file will be created or overwritten.Example #2: Saving a file with another file nameYou can use the -o or --output option followed by a file name you want to save the output.\$ curl -o my-readme-file \$ curl -o ~/save/to/other/path to the above example, the output file will be created or overwritten.Example #3: Saving a file using the output redirection operatorIn Linux, you can use the output redirection operator > to write the output to a specific file.\$ curl > ~/save/to/specific/pathIf you want to append the output to that file, you can use the output append operator >> instead.Example #4: Downloading multiple files with a single commandIf you want to download multiple files, you can add more -o or -O options:\$ curl \ -O \ -o file-2 \ -o file-3 #5: Dealing with the HTTP redirectionIf the target server responded with the HTTP redirection code (3xx) for the requested file, the local file you downloaded would be empty. In this case, you have to add the -L or --location option to tell cURL to follow the redirects.\$ curl -L -O can use the --max-redirs option to specify the maximum number of redirects will be followed to avoid infinite redirection-followings:\$ curl -L --max-redirs 10 -O this example, after 10 attempts, cURL will throw an error and abort the download process.Example #6: Speed limitingIf you want to limit the downloading speed, you can use the --limit-rate option to set the maximum number of bytes downloaded per second. The number of bytes can be abbreviated by appending a suffix: kilobytes (k or K), megabytes (m or M), and gigabytes (g or G).To limit 512 bytes/second and 2 megabytes/second:\$ curl --limit-rate 512 -O \$ curl --limit-rate 2M -O #7: Downloading a part of a filecURL allows you to download a part of a file by using the -r or --range option.For example, to get the first 500 bytes of a file:\$ curl -r 0-500 -O get the last 300 bytes of a file:\$ curl -r -300 -O #8: Resuming downloading a fileWhat would you do if the download process was interrupted, for example, you pressed Ctrl + C? Re-download?Do not! Because cURL supports resuming a file downloading process at the given offset by the -C option. If you do not know the exact value of the offset, do not worry, you just need to specify -C - to tell cURL to automatically find out that value.\$ curl -C - -O #9: Using basic authenticationIf the requested file requires basic authentication, you need to use the -u option followed by the credential which is in the form of user:password:\$ curl -u user:password -O read more about basic authentication, you can read the article 3 methods to use basic authentication with cURL.Example #10: Using a proxyIf you want to use a proxy to download a file, you need to use -x option followed by the proxy address, say :\$ curl -x -O see more examples, you can read the article How to use a proxy with cURL.Example #11: Entering the silent modeIf you do not want cURL to show the progress meter or error messages, you can use the -s or --silent option:\$ curl -s -O published at Tru BlogL O A D I N G . . . comments & more! Errors are the bane of users and programmers alike. Developers obviously don't want their programs falling over at every turn and users are now so used to having errors in programs that they grudgingly accept to pay the price for software that will almost certainly have at least one error in it. Java is designed to give the programmer a sporting chance in designing an error-free application. There are exceptions that the programmer will know are a possibility when an application interacts with a resource or a user and these exceptions can be handled. Unfortunately, there are exceptions the programmer can't control or simply overlooks. In short, all exceptions are not created equal and therefore there are several types for a programmer to think about. An exception is an event which causes the program to be unable to flow in its intended execution. There are three types of exception—the checked exception, the error and the runtime exception. Checked exceptions are exceptions that a Java application should be able to cope with. For example, If an application reads data from a file it should be able to handle the FileNotFoundException . After all, there is no guarantee that the expected file is going to be where it is supposed to be. Anything could happen on the file system, which an application would have no clue about. To take this example one step further. Let's say we are using the FileReader class to read a character file. If you have a look at the FileReader constructor definition in the java api you will see it's method signature: public FileReader(String fileName) throws FileNotFoundException As you can see the constructor specifically states that the FileReader constructor can throw a FileNotFoundException. This makes sense as it's highly likely that the fileName String will be wrong from time to time. Look at the following code: public static void main(String[] args){ FileReader fileInput = null; //Open the input file fileInput = new FileReader("Untitled.txt"); } Syntactically the statements are correct but this code will never compile. The compiler knows the FileReader constructor can throw a FileNotFoundException and it's up to the calling code to handle this exception. There are two choices - firstly we can pass the exception on from our method by specifying a throws clause too: public static void main(String[] args) throws FileNotFoundException{ FileReader fileInput = null; //Open the input file fileInput = new FileReader("Untitled.txt"); } Or we can actually handle with the exception: public static void main(String[] args){ FileReader fileInput = null; try { //Open the input file fileInput = new FileReader("Untitled.txt"); } catch(FileNotFoundException ex) { //tell the user to go and find the file } } Well-written Java applications should be able to cope with checked exceptions. The second kind of exception is known as the error. When an exception occurs the JVM will create an exception object. These objects all derive from the Throwable class. The Throwable class has two main subclasses—Error and Exception. The Error class denotes an exception that an application is not likely to be able to deal with. These exceptions are considered rare. For example, the JVM might run out of resources due to the hardware not being able to cope with all the processes it is having to deal with. It's possible for the application to catch the error to notify the user but typically the application is going to have to close until the underlying problem is dealt with. A runtime exception occurs simply because the programmer has made a mistake. You've written the code, it all looks good to the compiler and when you go to run the code, it falls over because it tried to access an element of an array that does not exist or a logic error caused a method to be called with a null value. Or any number of mistakes a programmer can make. But that's okay, we spot these exceptions by exhaustive testing, right? Errors and Runtime Exceptions fall into the category of unchecked exceptions.
